Newborn skin microbiome

The newborn skin microbiome is basically a tiny ecosystem of bacteria, fungi and viruses that starts forming right from birth. Most of these microbes come from the mother and the baby's immediate surroundings. Over the first two to three years of life, this community gradually grows and becomes more stable.[1]

A healthy skin microbiome acts like a natural defence system. It helps keep the skin slightly acidic, which makes it harder for harmful microbes to grow. It also plays a role in teaching the immune system how to respond to the outside world.[1]

Several everyday factors can influence how this microbiome develops. Skin-to-skin contact is one of the most important because it transfers beneficial microbes from parents and caregivers to the baby. Feeding also matters; breastfeeding can help support a more diverse and balanced microbiome. The baby's environment plays a role too, including contact with siblings, pets and normal household microbes.[1]

Gentle skincare is important during this stage. Washing too often or using harsh products can strip away the natural protective bacteria on the skin. Keeping things simple such as minimal bathing, mild products and plenty of skin-to-skin contact, helps support the healthy development of the newborn skin microbiome.[1,2,3]

Naturally calming calendula

Skincare containing Calendula is often well suited for the delicate skin of newborns and young children. Calendula is a lively, vibrant plant that combines warmth and moisture in the way it grows. Its bright yellow, orange and red flowers capture sunlight, while its soft, juicy leaves and stems contain a gentle, fragrant resin. The plant is rich in natural compounds that help calm inflammation, support the skin's healing process and encourage the growth of new tissue. These components also help strengthen the skin and protect it from environmental stress.[2]

In babies, the skin plays an important role in keeping the body warm and protecting developing organs. However, young skin is still learning to adapt to changes in temperature and the outside environment. With gentle care, warm clothing and soothing plant based treatments like calendula, baby skin can gradually build its strength and resilience while staying protected and comforted.[2,3]

Therapeutic touch

Touch and physical contact play an important role in how caregivers interact with babies, especially in helping them regulate their emotions and level of alertness. Even within the first two months of life, gentle, soothing touch can activate areas of a baby's brain involved in sensing the body and processing feelings like comfort or pain. Touch also helps strengthen the bond between parent and child and supports moments when they become emotionally in sync with each other.[4]

In early development, touch is especially important because it links what the body feels internally with what it senses from the outside world. This connection helps babies regulate their physical and emotional states. Positive touch can calm infants, slow their heart rate and support healthy breathing. Through these early experiences, babies begin to develop awareness of their bodies and start to understand themselves as individuals who are connected to others.[4] **TPM**
